TL;DR: In this paper , the authors used Indian sign language to identify elementary sign language gestures in images/videos and compared machine language methods to improve the performance of deployed models and achieved a higher accuracy of 84% and 83% precision compared to decision tree and KNN models.

Abstract: Sign language is a great visual communication technique for those who have auditory or speech impairments. The deaf and dumb people have long relied on sign language recognition (SLR) to communicate and integrate into society. This research uses Indian Sign Language to identify elementary sign-language gestures in images/videos and compares machine language methods. Images are pre-processed and feature-extracted to improve the performance of deployed models. The goal is to create a system that uses an efficient classifier to deliver reliable hand sign [read more](#)
